Contents

1 Range Operation Structures

1.1 Binary indexed tree

1.1.1 Point update, range query

Usage:

`init(n)`	Initialize the tree with 0.
`add(n, x)`	Add the n-th element by x.
`sum(n)`	Return the sum of the first n elements.

Time complexity: $O(n)$ for initialization; $O(\log n)$ for each update and query.

```
inline int lowbit(int x){return x&-x;}

struct bit_purq{ // point update, range query
    int N;
    vector<LL> tr;

    void init(int n){ // fill the array with 0
        tr.resize(N = n + 5);
    }

    LL sum(int n){
        LL ans = 0;
        while (n){
            ans += tr[n];
            n -= lowbit(n);
        }
        return ans;
    }

    void add(int n, LL x){
        while (n < N){
            tr[n] += x;
            n += lowbit(n);
        }
    }
};
```

1.1.2 Range update, point query

Usage:

`init(n)`	Initialize the tree with 0.
`add(n, x)`	Add the first n element by x.
`query(n)`	Return the value of the n-th element.

Time complexity: $O(n)$ for initialization; $O(\log n)$ for each update and query.

```
inline int lowbit(int x){return x&-x;}

struct bit_rupq{ // range update, point query
    int N;
    vector<LL> tr;

    void init(int n){ // fill the array with 0
        tr.resize(N = n + 5);
    }

    LL query(int n){
        LL ans = 0;
        while (n < N){
            ans += tr[n];
            n += lowbit(n);
        }
        return ans;
    }

    void add(int n, LL x){
        while (n){
            tr[n] += x;
            n -= lowbit(n);
        }
    }
};
```

1.1.3 Range update, range query

Usage:

`init(n)`	Initialize the tree with 0.
`add(l, r, x)`	Add the elements in $[l, r]$ by x.
`query(l, r)`	Return the sum of the elements in $[l, r]$.

Requirement:
1.1.1 Point update, range query

Time complexity: $O(n)$ for initialization; $O(\log n)$ for each update and query.

```
struct bit_rurq{
```

```
    bit_purq d, di;

    void init(int n){
        d.init(n); di.init(n);
    }

    void add(int l, int r, LL x){
        d.add(l, x); d.add(r+1, -x);
        di.add(l, x*l); di.add(r+1, -x*(r+1));
    }

    LL query(int l, int r){
        return (r+1)*d.sum(r) - di.sum(r) - l*d.sum(l-1) + di.sum(l-1);
    }
};
```

2 Miscellaneous Data Structures

2.1 Sparse table, range extremum query (RMQ)

Usage:

`ext(x, y)`	Return the extremum of x and y. **Modify this function before use!**
`init(n)`	Calculate the sparse table for array a from `a[0]` to `a[n-1]`.
`rmq(l, r)`	Query range extremum from `a[l]` to `a[r]`.

Time complexity: $O(n \log n)$ for initialization; $O(1)$ for each query.

```
const int MAXN = 100007;
int a[MAXN];
int st[MAXN][32 - __builtin_clz(MAXN)];

inline int ext(int x, int y){return x>y?x:y;} // ! max

void init(int n){
    int l = 31 - __builtin_clz(n);
    rep (i, n) st[i][0] = a[i];
    rep (j, l)
        rep (i, 1+n-(1<<j))
            st[i][j+1] = ext(st[i][j], st[i+(1<<j)][j]);
}

int rmq(int l, int r){
    int k = 31 - __builtin_clz(r-l+1);
    return ext(st[l][k], st[r-(1<<k)+1][k]);
```

```
}
```

3 Tree

3.1 Heavy-light decomposition

Usage:

`sz[x]`	Size of subtree rooted at x.
`top[x]`	Top node of the chain that x belongs to.
`fa[x]`	Father of x if exists; otherwise 0.
`son[x]`	Child node of x in its chain if exists; otherwise 0.
`depth[x]`	Depth of x. The depth of root is 1.
`id[x]`	Index of x used in data structure.
`decomp(r)`	Perform heavy-light decomposition on tree rooted at r.
`query(u, v)`	Query the path between u and v.

Time complexity: $O(n)$ for decomposition; $O(f(n)\log n)$ for each query, where $f(n)$ is the time-complexity of data structure.

```
const int MAXN = 100005;
vector<int> adj[MAXN];
int sz[MAXN], top[MAXN], fa[MAXN], son[MAXN], depth[MAXN], id[MAXN];

void dfs1(int x, int dep, int par){
    depth[x] = dep;
    sz[x] = 1;
    fa[x] = par;
    int maxn = 0, s = 0;
    for (int c: adj[x]){
        if (c == par) continue;
        dfs1(c, dep + 1, x);
        sz[x] += sz[c];
        if (sz[c] > maxn){
            maxn = sz[c];
            s = c;
        }
    }
    son[x] = s;
}

int cid = 0;
void dfs2(int x, int t){
    top[x] = t;
    id[x] = ++cid;
```

```
    if (son[x]) dfs2(son[x], t);
    for (int c: adj[x]){
        if (c == fa[x]) continue;
        if (c == son[x]) continue;
        else dfs2(c, c);
    }
}

void decomp(int root){
    dfs1(root, 1, 0);
    dfs2(root, root);
}

void query(int u, int v){
    while (top[u] != top[v]){
        if (depth[top[u]] < depth[top[v]]) swap(u, v);
        // id[top[u]] to id[u]
        u = fa[top[u]];
    }
    if (depth[u] > depth[v]) swap(u, v);
    // id[u] to id[v]
}
```

3.2 Order Statistics and Splay

⚠ Like `std::set`, this structure does not support multiple equivalent elements.

Usage:

See comments in code.

```
#include <ext/pb_ds/assoc_container.hpp>
using namespace __gnu_pbds;

tree<int, null_type, less<int>, rb_tree_tag, tree_order_statistics_node_update>
  rkt;
// null_tree_node_update

// SAMPLE USAGE
rkt.insert(x);          // insert element
rkt.erase(x);           // erase element
rkt.order_of_key(x);    // obtain the number of elements less than x
rkt.find_by_order(i);   // iterator to i-th (numbered from 0) smallest element
rkt.lower_bound(x);
rkt.upper_bound(x);
rkt.join(rkt2);         // merge tree (only if their ranges do not intersect)
rkt.split(x, rkt2);     // split all elements greater than x to rkt2
```

3.3 Persistent array

Usage:

`init(size, il)`	(Re)initialize an array of size `size` and initial values `il`.
`access(pos)`	Access the position with index `pos`.
`update(pos, val)`	Change the value at `pos` to `val`.

Time complexity: $O(\log n)$ per operation.

```
struct node {
  static int n, pos;

  union {
    int value;
    struct {
      node *left, *right;
    };
  };

  void* operator new(size_t size);

  static node* build(int l, int r, int* il) {
    node* a = new node;
    if (r > l + 1) {
      int mid = (l + r) / 2;
      a->left = build(l, mid, il);
      a->right = build(mid, r, il);
    } else {
      a->value = il[l];
    }
    return a;
  }

  static node* init(int size, int* il) {
    n = size;
    pos = 0;
    return build(0, n, il);
  }

  node *Update(int l, int r, int pos, int val) const {
    node* a = new node(*this);
    if (r > l + 1) {
      int mid = (l + r) / 2;
```

```
      if (pos < mid)
        a->left = left->Update(l, mid, pos, val);
      else
        a->right = right->Update(mid, r, pos, val);
    } else {
      a->value = val;
    }
    return a;
  }

  int Access(int l, int r, int pos) const {
    if (r > l + 1) {
      int mid = (l + r) / 2;
      if (pos < mid) return left->Access(l, mid, pos);
      else return right->Access(mid, r, pos);
    } else {
      return value;
    }
  }

  int access(int index) {
    return Access(0, n, index);
  }

  node *update(int index, int val) {
    return Update(0, n, index, val);
  }
} nodes[30000000];

int node::n, node::pos;
inline void* node::operator new(size_t size) {
  return nodes + (pos++);
}
```

3.4 Persistent union-find set

Persistent union-find set with union-by-rank.

Usage:

`init(size)`	(Re)initialize a ufs of size `size` with indices $[0, \text{size})$.
`find(pos)`	Get the parent of `pos`.
`unite(u, v)`	Unite the two sets containing `u`, `v`.

Time complexity: $O(\log^2 n)$ per operation.

```
// ~0.1s per 100000 operations @ luogu.org
struct node {
  static int n, pos;

  union {
    struct {
      int value, rank;
    };
    struct {
      node *left, *right;
    };
  };

  void* operator new(size_t size);

  static node* build(int l, int r) {
    node* a = new node;
    if (r > l + 1) {
      int mid = (l + r) / 2;
      a->left = build(l, mid);
      a->right = build(mid, r);
    } else {
      a->value = l;
      a->rank = 0;
    }
    return a;
  }

  static node* init(int size) {
    n = size;
    pos = 0;
    return build(0, n);
  }

  node *Update(int l, int r, int pos, node nd) {
    node* a = new node(*this);
    if (r > l + 1) {
      int mid = (l + r) / 2;
      if (pos < mid)
        a->left = left->Update(l, mid, pos, nd);
      else
        a->right = right->Update(mid, r, pos, nd);
    } else {
      *a = nd;
    }
    return a;
  }
```

```
48
49    node *Access(int l, int r, int pos) {
50      if (r > l + 1) {
51        int mid = (l + r) / 2;
52        if (pos < mid) return left->Access(l, mid, pos);
53        else return right->Access(mid, r, pos);
54      } else {
55        return this;
56      }
57    }
58
59    int find(int x) {
60      int fa;
61      while ((fa = Access(0, n, x)->value) != x)
62        x = fa;
63      return x;
64    }
65
66    node* unite(int u, int v) {
67      u = find(u); v = find(v);
68      if (u == v) return this;
69      int ru = Access(0, n, u)->rank, rv = Access(0, n, v)->rank;
70      if (ru == rv)
71        return Update(0, n, u, {v, ru})->Update(0, n, v, {v, ru+1});
72      if (ru > rv) {
73        swap(u, v);
74        swap(ru, rv);
75      }
76      return Update(0, n, u, {v, rv});
77    }
78  } nodes[20000000];
79
80  int node::n, node::pos;
81  inline void* node::operator new(size_t size) {
82    return nodes + (pos++);
83  }
```
