# 1 Number Theory

## 1.1 Modulo operations

### 1.1.1 Modular exponentiation (fast power-mod)

Calculate  $b^e \bmod m$ .

△ Cannot be performed on long long, unless use 1.1.3 Modular multiplication on long long .

**Time complexity:**  $O(\log e)$

```

1 LL powmod(LL b, LL e, LL m){
2     LL r = 1;
3     while (e){
4         if (e & 1) r = r * b % m;
5         b = b * b % m;
6         e >>= 1;
7     }
8     return r;
9 }
```

### 1.1.2 Mathematical modulo operation

The result has the same sign as divisor.

```

1 inline LL mathmod(LL a, LL b){
2     return (a % b + b) % b;
3 }
```

### 1.1.3 Modular multiplication on long long

Calculate  $ab \bmod m$ , where  $a, b, m$  are long long integers.

△  $a, b, m$  must be non-negative.

**Time complexity:**  $O(\log b)$

```

1 LL mulmod(LL a, LL b, LL m){
2     LL r = 0;
3     a %= m; b %= m;
4     while(b) {
5         if(b & 1) r += a, r %= m;
```

```

6      b >>= 1;
7      if(a < m - a)
8          a <<= 1;
9      else
10         a -= (m - a);
11    }
12    return r;
13 }

```

## 1.2 Extended Euclidian algorithm

Solve  $ax + by = g = \gcd(a, b)$  w.r.t.  $x, y$ .

If  $(x_0, y_0)$  is an integer solution of  $ax + by = g = \gcd(x, y)$ , then every integer solution of it can be written as  $(x_0 + kb', y_0 - ka')$ , where  $a' = a/g$ ,  $b' = b/g$ , and  $k$  is arbitrary integer.

$\triangle$   $x$  and  $y$  must be positive.

### Usage:

`exgcd(a, b, g, x, y)` Find a special solution to  $ax + by = g = \gcd(a, b)$ .

**Time complexity:**  $O(\log \min\{a, b\})$

```

1 void exgcd(LL a, LL b, LL &g, LL &x, LL &y){
2     if (!b) g = a, x = 1, y = 0;
3     else exgcd(b, a % b, g, y, x), y -= x * (a / b);
4 }

```

### 1.2.1 Modular multiplicative inverse

An integer  $a$  has modular multiplicative inverse w.r.t. the modulus  $m$ , iff  $\gcd(a, m) = 1$ . Assume the inverse is  $x$ , then

$$ax \equiv 1 \pmod{m}.$$

Call `exgcd(a, m, g, x, y)`, if  $g = 1$ ,  $x + km$  is the modular multiplicative inverse of  $a$  w.r.t. the modulus  $m$ .

```

1 inline LL minv(LL a, LL m){
2     LL g, x, y;
3     exgcd(a, m, g, x, y);
4     return (x % m + m) % m;
5 }

```

Or, by Fermat's little theorem ( $a^p \equiv a \pmod{p}$ ), when  $m$  is a prime, the multiplicative can also be written as  $a^{-1} = (a^{p-2} \pmod{p})$ .

### 1.3 Primality test (Miller-Rabin)

Test whether  $n$  is a prime.

The array `a[]` (excluding sentinel, e.g. `LLONG_MAX`) should be

<code>{2}</code>	when $n < 2,047$ .
<code>{2, 7, 61}</code>	when $n < 4,759,123,141$ ( $2^{32}$ ).
<code>{2, 3, 5, 7, 11}</code>	when $n < 2.1 \times 10^{12}$ .
<code>{2, 325, 9375, 28178, 450775, 9780504, 1795265022}</code>	when $n < 2^{64}$ .

△ When  $n$  exceeds the range of `int`, the `mul-mod` and `pow-mod` operations should be rewritten.

#### Requirement:

1.1.1 Modular exponentiation (fast power-mod)

**Time complexity:**  $O(\log n)$

```

1 bool test(LL n){
2     if (n < 3) return n==2;
3     // ! The array a[] should be modified if the range of x changes.
4     const LL a[] = {2LL, 7LL, 61LL, LLONG_MAX};
5     LL r = 0, d = n-1, x;
6     while (~d & 1) d >>= 1, r++;
7     for (int i=0; a[i] < n; i++){
8         x = powmod(a[i], d, n);
9         if (x == 1 || x == n-1) goto next;
10        rep (i, r) {
11            x = (x * x) % n;
12            if (x == n-1) goto next;
13        }
14        return false;
15 next:;
16    }
17    return true;
18 }
```

## 1.4 Sieve of Eratosthenes

## 1.5 Chinese remainder theorem

## 1.6 Quadratic residue

### 1.6.1 Legendre symbol

For non-negative integer  $a$  and **odd** prime  $p$ , the Legendre symbol is defined as

$$\left(\frac{a}{p}\right) = \begin{cases} 0 & \text{if } a \mid p \\ 1 & \text{if } a \nmid p \text{ and } a \text{ is a quadratic residue modulo } p \\ p-1 & \text{if } a \nmid p \text{ and } a \text{ is a quadratic non-residue modulo } p \end{cases}$$

Call `powmod(a, (p-1)/2, p)` to calculate Legendre symbol.

# 2 Linear Algebra

## 2.1 Modular exponentiation of matrices

Calculate  $b^e \bmod \text{modular}$ , where  $b$  is a matrix. The modulus is element-wise.

**Usage:**

<code>n</code>	Order of matrices.
<code>modular</code>	The divisor in modulo operations.
<code>m_powmod(b, e)</code>	Calculate $b^e \bmod \text{modular}$ . The result is stored in <code>r</code> .

**Time complexity:**  $O(n^3 \log e)$

```

1  const int MAXN = 105;
2  const LL modular = 1000000007;
3  int n; // order of matrices
4
5  struct matrix{
6      LL m[MAXN][MAXN];
7
8      void operator *=(matrix& a){
9          static LL t[MAXN][MAXN];
10         Rep (i, n){
11             Rep (j, n){
12                 t[i][j] = 0;
13                 Rep (k, n){
14                     t[i][j] += (m[i][k] * a.m[k][j]) % modular;

```

```
15         t[i][j] %= modular;
16     }
17 }
18 }
19 memcpy(m, t, sizeof(t));
20 }
21 };
22
23 matrix r;
24 void m_powmod(matrix& b, LL e){
25     memset(r.m, sizeof(r.m), 0);
26     Rep(i, n)
27         r.m[i][i] = 1;
28     while (e){
29         if (e & 1) r *= b;
30         b *= b;
31         e >>= 1;
32     }
33 }
```

## 3 Combinatorics

### 3.1 Pólya enumeration theorem
